Let's get started by adding your first contact.

CONTACT 1
Enter first and last name: Beverly Dupuis
Enter phone number: 2297489172
Enter email address: BeverlyADupuis@hotmail.com
Enter physical address: 2847 Locust Street, Valdosta, GA 31601

Keep going? Type 1 for yes and 0 for no: 1

CONTACT 2
Enter first and last name: Arthur Cunningham
Enter phone number: 6023583469
Enter email address: Fantasticonicorn1990@gmail.com
Enter physical address: 4870 Dye Street, Tempe, AZ 85281

Keep going? Type 1 for yes and 0 for no: 1

CONTACT 3
Enter first and last name: Dillon Seward
Enter phone number: 6023618728
Enter email address: sewarddgi@grinnell.edu
Enter physical address: 1115 Eighth Ave, Grinnell, IA 50112

Keep going? Type 1 for yes and 0 for no: 1

CONTACT 4
Enter first and last name: Zippora Hardwick
Enter phone number: 4072795628
Enter email address: zippynardwick@gmail.com
Enter physical address: 1028 Virgil Street, Fort Walton Beach, FL 32548

Keep going? Type 1 for yes and 0 for no: 1

CONTACT 5
Enter first and last name: Joanna Deering
Enter phone number: 4242873729
Enter email address: deering@larealestate.com
Enter physical address: 2119 Edsel Rd, Los Angeles, CA 90017

Keep going? Type 1 for yes and 0 for no: 0
```

Test 1, Part 1 for **Problem 3, Contact Info**. Here I enter sample contact information for five people: full name, phone number, email address, and physical address. There are a few contingencies this program doesn't support, like names that are three words and above and addresses that don't conform to the prescribed format. Phone numbers must be entered as a string of ten digits without delimiters. The program corrects capitalization errors but not typos.

It checks in with the user after every contact to confirm they want to keep adding. Another way I could have done this is by asking first thing for the number of contacts to be added. While `i < range(number_to_add)`, continue adding.

```

Test 1, Part 2 for **Problem 3, Contact Info**. Ending the contact adding loop allows the program to display a list of actions the user can take next. For 'all' or 'ALL', a table with all contacts' complete information is printed. For 'phone', just the names and phone numbers are printed.

```

Test 1, Part 3 for **Problem 3, Contact Info**. For 'places', a table with all contacts' names and locations are printed. Location is an abbreviated version of address with just city and state. It's found by drilling down into the third dimension of the master ContactList, which was populated during the contact adding stage with address components in isolation. The algorithm pulls just city and state and reformats them in one f-string.

For a full name (sensed as a string input containing two words/one middle space), just phone number is output.

```

```

The screenshot shows a Visual Studio Code editor window with a Python file named `MiaoAria_Problem3_ContactInfo.py`. The code defines a `store_name` function that takes a user name, splits it into first and last names, and stores them in a dictionary. It also includes error handling for names that are not in the "First Last" format. The terminal output shows the program being run from a command prompt, with the user entering a name, a phone number, and an address, and the program responding with prompts and error messages.

```
1 def store_name(user_name): # Define a method for storing names from user input
2     # Assume names are inputted in the format "First Last"; standardize
3     user_name = user_name.strip().lower().title()
4     name_list = user_name.split()
5     name_dict = {'last': None, 'first': None}
6
7     # To distinguish between first and last, store name values in a dict
8     # that will compose one dimension of the three-dimensional master list
9     if len(name_list) == 2:
10         for i in range(len(name_list)):
11             if i == 0:
12                 name_dict['first'] = name_list[i]
13             else:
14                 name_dict['last'] = name_list[i]
15     else:
16         print('\nERROR: Please enter name in the format "First Last.\n')
17         quit() # Program doesn't allow for names three words and above
18
19     return name_dict
20
```

Let's get started by adding your first contact.

CONTACT 1
Enter first and last name: Jane Emily Doe

ERROR: Please enter name in the format "First Last."

PS C:\Users\ariax> & C:/Users/ariax/AppData/Local/Microsoft/WindowsApps/python3.11.exe "c:/Users/ariax/Downloads/Mini-Project 2/MiaoAria_Problem3_ContactInfo.py"

Let's get started by adding your first contact.

CONTACT 1
Enter first and last name: Jane Doe
Enter phone number: 888-888-8888

ERROR: Please enter phone number as ten unbroken digits.

PS C:\Users\ariax> & C:/Users/ariax/AppData/Local/Microsoft/WindowsApps/python3.11.exe "c:/Users/ariax/Downloads/Mini-Project 2/MiaoAria_Problem3_ContactInfo.py"

Let's get started by adding your first contact.

CONTACT 1
Enter first and last name: Jane Doe
Enter phone number: 8888888888
Enter email address: janedoe@gmail.com
Enter physical address: 111 Main St, Apt 36A, Greenville, AK 12345

ERROR: Please enter address in the format "Street, City, State Zip."

PS C:\Users\ariax>

Test 2 for **Problem 3, Contact Info**. Here I refresh the contact list with one generic contact. I enter a phone number in an unsupported format to elicit the error message, then an address in an unsupported format to elicit the error message.

The image shows a Visual Studio Code editor window with a Python script named `MiaoAria_Problem3_ContactInfo.py` open. The script defines a `store_name` function that takes a user name, strips whitespace, converts to lowercase, and splits it into first and last names. It then stores these in a dictionary. The main program prompts the user to enter a name in the format "First Last".

```
1 def store_name(user_name): # Define a method for storing names from user input
2     # Assume names are inputted in the format "First Last"; standardize
3     user_name = user_name.strip().lower().title()
4     name_list = user_name.split()
5     name_dict = {'last': None, 'first': None}
6
7     # To distinguish between first and last, store name values in a dict
8     # that will compose one dimension of the three-dimensional master list
9     if len(name_list) == 2:
10         for i in range(len(name_list)):
11             if i == 0:
12                 name_dict['first'] = name_list[i]
13             else:
14                 name_dict['last'] = name_list[i]
15     else:
16         print('\nERROR: Please enter name in the format "First Last.\n')
17         quit() # Program doesn't allow for names three words and above
18
19     return name_dict
20
21
```

The terminal output shows the program running. It prompts the user to enter a name, and the user enters "jane doe". The program then prompts for phone number, email address, and physical address. The user enters "888888888", "janedoe@gmail.com", and "111 main st, greenville, ak 12345". The program then displays a menu of options for the user to choose from.

```
PS C:\Users\ar1ax> & C:\Users\ar1ax\AppData\Local\Microsoft\WindowsApps\python3.11.exe "c:/Users/ar1ax/Downloads/Mini-Project 2/MiaoAria_Problem3_ContactInfo.py"

Let's get started by adding your first contact.

CONTACT 1
Enter first and last name: jane doe
Enter phone number: 888888888
Enter email address: janedoe@gmail.com
Enter physical address: 111 main st, greenville, ak 12345

```

Test 4 for **Problem 3, Contact Info**. Here I enter a three-word string not found in the list of options to elicit an error message. One- and two-word entries not preprogrammed into the list are sensed as name inputs that ask for a full address or phone number. While the contact list is scanned automatically under these circumstances, the program returns an error message if the name is not found (in this case, misspelled). Capitalization doesn't matter.
